BETTEX — community, rules and administration

Summary of rules and administration. The complete chapters, drawings and technical references are in the site's documentation. This file does not prove deployment or financial operation.

https://bettex.ai/en/documentation

Legal and regulatory compliance

Every BETTEX launch must already comply with the legal environment of the markets where the solution will be offered. Releasing each agent, feature and category requires a specific technical and legal investigation and compliance with applicable requirements. A roadmap date does not replace this condition.

The assessment identifies the country of offering, target audience, activity, responsible parties and providers. Offering and execution are assessed separately; permission in one country does not authorize activity in another. If an activity requires a license or authorization, it will not be released before those requirements are met.

The investigation verifies official sources, validity and scope of necessary norms, licenses and authorizations, provider terms, advertising, user protection, identification and anti-money laundering prevention, data protection, and applicable responsibilities. Legal and technical personnel record the evidence, the analysis date, conditions, and required controls.

Each combination of agent, activity and territory must have its scope documented: under investigation, restricted or authorized for launch. Release requires a favorable legal assessment, authorizations where required and validated technical controls. A pending investigation, prohibition or missing required authorization prevents offering and operation in that territory.

If casino or iGaming is prohibited in Brazil at the time of the offering, that category will not be offered to the Brazilian audience. If prediction markets cannot legally be offered in Brazil, agents in that category will not be released for that market. These are conditional examples: the conclusion depends on a current investigation of the specific activity, not a general statement in this documentation.

The assessment also covers token minting and offering, advertising, in-app games, financial services and each integration. API availability, blockchain use, a foreign license or a partner launchpad do not replace local authorization. Mint authorization does not automatically authorize agents or other features.

Before each expansion, compliance is reassessed for the new territory and activity. Regulatory, license, provider or product changes require review. Loss of a required condition suspends affected new offerings and operations; existing positions and obligations receive specific treatment under legal guidance and risk controls.

Territorial availability conditions must be communicated to users and reflected in eligibility, access and execution controls. Evidence, responsible parties, conditions, validity or review

periods and decisions are recorded. This section defines launch requirements; it does not claim licenses obtained, completed legal opinions or authorized agents.

Financing: sources and uses of funds

Angel contributions allocate 100% of funds to product, technology and marketing, with no founder salaries or withdrawals. The 15% token allocation does not impose a funding split: agreements identify sources, uses and rights.

The initial fixed-price mint funds the project; price, window and platform are yet to be defined, with legal compliance. Sales of released community tokens send 100% of the USDC price to the treasury. Investor contributions have their own terms and fund product, technology and marketing, with no salaries. Fundraising is not distributable profit.

The price belongs to the seller. It creates no new funding or treasury profit and does not accelerate vesting.

BETTEX does not charge service fees. Real transactions may require external network costs, which are not community revenue.

Burn Lottery and Double 2X

Burn Lottery: one free number per wallet with staked BETTEX; extra entries paid in BETTEX and fully burned, funding neither prizes nor operating revenue. There is no business cap on numbers. Payment is a BETTEX exit: all prior weight resets and all prior unpaid round credits are cancelled; received USDC remains personal.

Double 2X: optional red or black game using USDC earnings already received, without pending credits. One play per rolling 24 hours, 50/50 outcome and no game fee. With 10 USDC played, a win returns 20 in total, a net gain of 10 paid by the treasury; a loss returns zero and sends the 10 to the treasury. A theoretical 100% RTP does not guarantee gains per play.

Lottery rules must identify price, prize, funding, timing and odds before accepting entries. The games are neither investment strategies nor promises of yield; simulated results do not prove execution, public randomness or settlement.

Operational round and demonstration

The operational model has daily UTC rounds. Market tabs do not create separate staking pools.

Administration and purpose

BETTEX is an open community building DeFi technology and AI agents. BETTEX is the community token, with no company or foundation, salaries or service fees. Resources and development serve a community purpose; personal wallets remain the property of their holders.

Founders initially administer the project and retain control of the contracts. Functions gradually pass to AI, with evidence and limits and no defined deadline. This does not transfer

contract control.

Community participation in decisions is yet to be defined. No DAO, token voting or ownership relinquishment has been defined.

The founder and team organize the community's initial administration. AI agents will gradually take on functions until the BETTEX agent becomes operationally independent and autonomous. This is a future goal and does not remove applicable controls or responsibilities.

Transparency, responsibility and accountability guide the operation, with no guaranteed income or capital protection.

Token, funding, and burn

Cap of 1 billion BETTEX in four allocations: 10% initial public mint, 55% community, 20% founder/team and 15% investors. The mint is open at a fixed price and funds the project. The price, window, platform and destination of the unminted portion remain to be defined.

Public mint planned for December 10, 2026. System/ALPHA and vesting start planned for March 2027. Each launch requires legal compliance by activity and territory.

Vesting of 900 million BETTEX over 24 months from March 2027: community 550 million, founder/team 200 million and investors 150 million, in whole-token 11:4:3 groups. The initial cap of 100 million remains separate; release does not prove sales or circulation.

100% of the USDC price of the already released community tokens goes to the treasury. BETTEX does not charge service fees. The initial mint funding finances the project and requires accountability. External markets do not automatically inherit the conditions of the official swap.

Eligible result, after reconciliation and controls, receives 50% treasury, 25% staking, and 25% exclusive buyback wallet. Without sufficient weights, reserves, or liquidity, 100% remains in the treasury, without future split. Purchase uses administrative authorization; all acquired BETTEX is permanently burned. Exclusive wallet is not the burn mechanism.

Staking and liquidation

Anyone joining during a round receives zero from that round, even for profit generated after joining, and participates only in the next. The confirmed eligible balance is fixed at opening; increases during the round participate only in the following round.

Individual weight = BETTEX eligible at opening x full round duration, with no exit. New participants and balances received during a round have zero weight in it; top-ups do not change the weight of the already eligible balance. Any exit resets all of the holder's weight; participation resumes only in the next round. Gross payment = staking share x individual weight / sum of eligible weights.

Example: A starts the round with 1,000 eligible BETTEX; B receives 1,000 at 12:00. With

eligible profit of 1,000 USDC and conditions met, the 250 USDC staking share pays 250 to A and zero to B. In the next round, both eligible from opening and with no exits receive 125 USDC each from new eligible profit of 1,000 USDC. No previous profit is recovered.

Each round pays or does not pay, without accumulation, reopening, or future supplement. Any BETTEX exit, including partial, resets the weight and cancels unpaid rights. Non-executable fractions return to the treasury, without future credit. Received USDC remains personal.

USDC credit depends on eligibility, round authorization, confirmation, and reconciliation. An authorization is not equivalent to receipt. Closing does not retain future credits, and uncertain transfers are not released by presumption.

Only confirmed and reconciled USDC enters the available balance. Uncertain sends do not authorize repetition nor are they recovered resources. Corrections maintain history and unique effects, without automatic debit from the personal wallet.

Governance and integrations

Policies evolve through approved versions. Administration defines policy; 2-of-3 multisig controls custody; executors act within mandates. Sensitive changes wait at least 24h; already mandated routine does not require new signature per operation. AI does not expand its own permissions.

Treasury, operational cash, exclusive buyback wallet, and personal wallets have their own boundaries. Defensive reserve follows the approved policy, without a general minimum fixed at 50%. New operations require independent risk, availability, and reconciliation.

Starknet and Arbitrum One are network and contract alternatives. BETTEX is in planning and grants fundraising, with no network chosen or presumed approved grant. Starknet requires Cairo implementation and compatible accounts; Arbitrum uses EVM. Allora is a candidate for inferences, not execution. Robinhood Crypto Trading API requires an eligible US account and authorization; it does not prove access to stocks. Arbitrum/Gamma public queries were verified; this does not define the launch network. Other examples without private access are simulations. No real money operations have occurred.

Economic period, settlement and financial closing

The economic period of the round is the UTC interval between 00:00, inclusive, and 00:00 of the following day, exclusive. The cut ends the collection of results and the eligible time of that round, not its settlement phase. After the cut, assessment and identified payments remain linked exclusively to the original round, while the following economic period is already underway.

Before operating, the approved policy must set the maximum reconciliation and execution window, the financial closing deadline, the sources, and the confirmation criteria. The window cannot be extended by participant, delay, or management convenience. Without these validated parameters and controls, there is no authorization to distribute. Financial closing is the end of this window or the registered early conclusion of all scheduled payments and treatments.

The weight is only calculated after the cut, with the eligible balance of the opening and the confirmed events of the entire economic period. Entries during the period wait for the next round; any exit during it resets the full weight to zero. Exits after the cut also cancel rights of the original round not yet paid, without altering the weights or results of the new round through old credit.

The indivisible assessment decision fixes the beneficiaries, weights and distribution denominator, also considering exits already confirmed by that decision. Later exits cancel the corresponding credit without recalculating other participants' allocations or redistributing the cancelled amount. The current zeroed weight and the historical calculation record are separate records. Repeating a decision does not create another split.

Calculation, authorization, and execution are stages of the same round, not a new distribution. Do not mix results, beneficiaries, or installments from different rounds. Financial closing eliminates rights provenly not sent; shipments already initiated or uncertain remain only in reconciliation. There is no supplement, reopening, or future credit after this closing.

The executor does not choose beneficiaries by convenience. The payment plan pre-registers deterministic order, installments, resources, and a common deadline; it uses atomic execution when validated for the network. If there is partial processing, it publishes who received, who did not receive, and the cause. Operational failure or underpayment can cause definitive loss of the installment not sent at financial closure: this risk must be informed before participation. Equality of receipt is not promised when the execution is not atomic.

BETTEX exit and payment order

The relevant order is that of the facts proven on the network, not the arrival of messages to the backend. A BETTEX exit prior to the effective receipt of USDC cancels the right not yet paid. Effective receipt prior to the exit remains personal, after confirmation and reconciliation. The policy registers the criteria for network ordering and finalization; equal times or insufficient evidence keep the case under verification.

A reserve or indivisible transaction in the bank does not prevent an external transfer made by the holder. The implementation must validate eligibility in the effective payment path, with orderable BETTEX and USDC events and a network-compatible mechanism that prevents paying an already cancelled right. An off-chain verification prior to submission, alone, does not prove this guarantee. Without validation of this mechanism, the automatic payment is not released.

Canceling a right does not reverse a transfer already initiated nor prove USDC recovery. An initiated or uncertain shipment is never repeated by presumption. If reconciliation proves undue receipt after a previous departure, register the undue payment and the treasury loss, without restoring the canceled right, automatically charging the personal wallet or creating another split. The USDC already received is not recovered by accounting adjustment.

Settlement costs and temporal origin

The economic result is cut before the payment phase. Effective costs belong to the UTC period

of their proven realization: settlement costs executed after the cut enter the result of the economic period in which they occurred, not retroactively into the profit that originated that payment. Register the payment round and the economic period of the cost separately, without accounting for the same fact twice.

Before authorizing the split, reserve principal and cost ceiling in each asset and project the liquidity after all disbursements. The cost reserve is not a realized expense. Its source and authorization are identified; costs are not silently deducted from the participant's right nor from the exclusive repurchase portion. Differences between reserved and effective cost are reconciled; the remainder is not new profit. If there is not sufficient budget and coverage, do not authorize the split.

External network or third-party costs are not BETTEX service fees. Development and maintenance costs remain open. This settlement rule does not authorize using the treasury for general expenses, changing the 50%/25%/25% split, or reopening a closed round.

The round profit is not a capital recovery.

There is no compensation for past losses nor a requirement to recover the previous peak equity to distribute. It is an economic choice of the model, not capital protection. New profit can be distributed with equity still below the previous value, only if defensive reserve, liquidity, and other conditions are met.

Hypothetical example in USDC, without other movements or costs: equity of 100 drops to 80 after a loss of 20; a new profit of 10 brings it to 90. Given conditions for the split, 2.5 go to participants, 2.5 to buyback, and 5 are retained. The operational equity ends at 85 and, added to the segregated buyback USDC, the project equity is 87.5, still below 100. Partial recovery does not guarantee token appreciation. Eligible participants of the new round may differ from those who were present during the loss.

Eligibility, exposure and game conditions

Burn Lottery keeps one free number per wallet, not per person. The regulation must set the cutoff and the eligible balance condition in staking, using a verifiable snapshot and a unique identifier per wallet and draw; transferring after the cutoff does not generate another free number in that draw. A person can control multiple eligible wallets: do not present this rule as protection against multiple identities. The prize budget must consider this possibility, without assuming a limit per person or a minimum balance not yet approved.

The Burn Lottery prize and the costs of the draw require an approved source and coverage before accepting entries. The paid BETTEX are burned and do not finance the prize. Payment, burn reference and entry generation must have a single effect and a verifiable recovery mechanism; if this link cannot be guaranteed, do not accept payments. The regulation informs the draw, verifiable randomness, fault handling and the impossibility of undoing a burn by simple adjustment.

Double 2X requires its own mandate with maximum bet, aggregate budget, reserve for simultaneous wins, timeframe, verifiable randomness, and failure procedure. These parameters must be

approved and published before opening; without them, the game is unavailable. The authorization grants the entire bet and reserves the obligation to return 2x, considering the bet received and the additional portion from the treasury, without using resources from staking, buyback, or other commitments.

USDC of yields already received is controlled by a reconciled source limit, not by the physical identity of the fungible tokens. Confirmed distributions increase this limit; each USDC withdrawal, including a bet, reduces it once down to zero. External deposits and game wins do not increase the limit. It never exceeds the free USDC balance; bet reserves prevent concurrent reuse. Insufficient evidence blocks the bet.

The rule of one play every 24 consecutive hours is applied to the official wallet linked to the account; changing sessions, devices, or recovering access does not reset the deadline. It is not a limit proven by person: multiple wallets are considered in the aggregate budget. Register the start a single time before execution; an uncertain attempt does not allow another play nor does it release the reserve by presumption.

The 100% RTP is gross and theoretical: it does not cover gas, randomness, nor guarantee cash equilibrium in the short term. Receipts, obligations, gains, losses, and game costs have their own ledger, reconciled with treasury equity. They do not enter as strategy profit eligible for split nor use the exclusive buyback budget. Equity variations of the games affect the reserve and liquidity controls before new operations and distributions.

Authentication and legal eligibility

Proving wallet control authenticates access, but does not prove civil identity, residence, age, or eligibility for an offer. Wallet login does not waive identification, KYC, or other controls when required for the activity and territory. The visual demo does not offer financial operations.

Legal investigation defines which controls are necessary for mint, participation, games, and integrations. Verifications from an external provider are not automatically sufficient for BETTEX obligations. Without validated required controls, restrict the supply and the affected operation; do not promise financial access without documents in any territory.
