BETTEX — entity, pilot, and rules

Company and administration

BETTEX is a technology product that combines an app, a token and AI agents. The user participates in the project's results according to the token rules, without ownership of the company or treasury.

A single private, closely-held commercial company to be incorporated, managed by the founder Fred Azevedo in a full stack AI model, with no employees. Specialized external services are contracted by need, not internal positions.

The company brings together the token, application, treasury, investments, and program obligations. Final name, corporate structure, and jurisdiction are part of the formalization. Holders own tokens and program rights, not shares, corporate voting, or a redeemable fraction of the treasury.

The mission expands alternatives for economic participation during the transition of AI and robotics. Transparency, understanding, responsibility, and accountability guide the operation, without guaranteed income or capital protection.

Pilot and revenue

Pilot capital: US$ 100k, with US$ 50k for treasury and US$ 50k for launch. Three-month goal: 5,000 users and 1,000 MAU. Investor contributions have free allocation; the pilot's destination is not a general split.

Fred drives acquisition through his own channels and audience, with AI and necessary external services. Launch includes boosting, partnerships, security, and paid media on the founder's profiles and own networks.

Service revenue = charged operations x US$ 2.50. Scenarios of 1, 10, and 30 operations per asset consider 1,000 MAU; 30 illustrates daily withdrawals, without presuming balance or adoption. Revenue is not profit: identified costs and taxes come before the net amount. No monthly budget or break-even date is presumed.

Token, funding, and burn

1 billion BETTEX issuance: 65% public sale, 20% Founder and team, 15% investors. Monthly vesting for 36 months since public sale opening, with whole groups 13:4:3. Release does not prove sale or circulation.

100% of the public sale price in USDC goes to the treasury. Separate service fees go to the operating cash. External markets do not automatically inherit the conditions of the official swap.

Eligible result, after taxes and controls, receives 50% to treasury, 25% to staking, and 25% to the exclusive buyback wallet. Without sufficient weights, reserves, or liquidity, 100% remains

in the treasury, without future split. Purchase uses administrative authorization; all acquired BETTEX is burned permanently. The exclusive wallet is not the burn mechanism.

Staking and fiscal sequence

BETTEX available in the official wallet participates automatically. Individual weight = sum of quantity x eligible time. Gross payment = staking share x individual weight / sum of eligible weights for the specific UTC round.

Each round pays or does not pay, without accumulation, reopening, or future supplement. Any BETTEX exit, including partial, resets the weight and cancels unpaid rights. Non-executable fractions return to the treasury, without future credit. Received USDC remains personal.

Taxes attributable to the entity are calculated, deducted, and paid according to the applicable obligation before eligible profit and split. Applicable withholdings are resolved before the net credit. Provision is not payment; accounting for and paying the same obligation does not allow double deduction. There is no universal personal exemption.

Only confirmed and reconciled USDC enters the available balance. Uncertain sends do not authorize repetition nor are they recovered resources. Corrections maintain history and unique effects, without automatic debit from the personal wallet.

Governance and integrations

Policies evolve through approved versions. Administration defines policy; 2-of-3 multisig controls custody; executors act within mandates. Sensitive changes wait at least 24h; already mandated routine does not require new signature per operation. AI does not expand its own permissions.

Treasury, operational cash, exclusive buyback wallet, and personal wallets have their own boundaries. Defensive reserve follows the approved policy, without a general minimum fixed at 50%. New operations require independent risk, availability, and reconciliation.

Arbitrum provides the network and contracts. Allora is a candidate for inferences, not execution. Robinhood Crypto Trading API requires an eligible account in the United States and authorization; it does not prove access to stocks. Arbitrum/Gamma public queries were verified; other examples without private access are simulations. No real money operations took place.
