BETTEX — Demo and proof of concept

This documentation accompanies the BETTEX demo and proof of concept. It records the architecture and its initial rules as a starting point; it does not certify a financial operation nor an ALFA version already delivered.

The next step is to document the ALFA version, after consulting the community and testing demo receptivity. Feedback from this stage will guide the definition of the next version.

Summary of rules and administration. The complete chapters, drawings and technical references are in the site's documentation. This file does not prove deployment or financial operation.

BETTEX agent and subagents

BETTEX is the orchestration agent of the decentralized multiagent architecture described in this documentation. Its focus is to coordinate analyses and build decisions with direct support from risk and treasury subagents. Each market’s trading subagents present proposals and evidence; risk and treasury support their evaluation before allocation or execution decisions. The governance subagent tracks policies and documentation. BETTEX system identifies the complete architecture; BETTEX agent identifies its central orchestration intelligence.

The risk subagent investigates exposure, loss scenarios and whether proposals fit current limits. The treasury subagent analyzes capital, reserves, liquidity and commitments to inform the availability and allocation of funds. Both produce analyses and inferences to support the BETTEX agent’s decisions, and may challenge hypotheses, share evidence and request further analyses. They are not merely parameter checkers or independent versions of BETTEX. Orchestration does not remove independent risk validation or authorize bypassing controls.

Governance: interpret and propose evolution

The governance subagent maintains and updates the BETTEX system documentation. It tracks approved decisions and changes, reviews chapters and their translations, records versions and preserves consistency between documentation, implementation and rules in force. Updating documentation does not approve policies or change permissions or economic rights.

Legal and regulatory compliance

Launches must comply with local laws. Subagents and features depend on technical-legal investigation and fulfillment of requirements, regardless of roadmap dates.

Trading, governance, risk and treasury subagents require analysis by country, activity and responsible party. Permissions are not universal; activities requiring licensing are released only with authorization.

Investigations verify regulations, licenses, terms, advertising, user protection, AML, privacy, and responsibilities, with formal recording of evidence, dates, and required controls.

Each combination (agent, activity, territory) requires a documented scope (investigating, restricted, or authorized). Lack of authorization or pending investigation blocks the operation in the territory.

Categories prohibited in Brazil (such as casino or unlicensed prediction) will not be offered. Examples are conditional, depending on the investigation of each specific activity.

Assessment covers mint, token, advertising, games, services, and integrations. APIs, blockchain, or foreign licenses do not replace the required local authorization.

Expansions require re-evaluation. Regulatory or product changes suspend affected offers, with existing positions handled according to legal guidance and risk controls.

Availability conditions must be disclosed to users and reflected in controls. This section defines launch requirements, it does not certify licenses or completed legal opinions.

Financing: sources and uses of funds

Angel contributions allocate 100% of funds to product, technology, and marketing, with no founder salaries or withdrawals. The 15% token allocation does not impose a funding split: terms identify origin, destination, and rights.

The initial mint finances the project at a fixed price; price, platform, and window definitions follow legal adequacy. Community token sales send 100% in USDC to the treasury. Investor contributions fund product, technology, and marketing, with no salaries; they are not distributable profit.

BETTEX does not charge service fees. Real transactions may incur external network costs, which are not community revenue.

Burn Lottery and Double 2X

Burn Lottery: one free number per wallet with BETTEX in staking; extras are paid in BETTEX and fully burned. Payment is a BETTEX outflow: it resets prior weight and cancels all prior unpaid credits of the round; received USDC remains personal.

Double 2X: optional red-or-black game using USDC from already received earnings, without pending credits. One play every 24 consecutive hours, a 50/50 result, and no game fee. With 10 USDC played, a win returns 20 total, a net gain of 10 paid by the treasury; a loss returns zero and sends the 10 to the treasury. A theoretical 100% RTP does not guarantee profit per play.

Lottery rules must identify price, prize, funding, deadline, and probabilities before accepting entries. Games are neither investment strategies nor a promise of returns; simulated results do not prove execution, public randomness, or settlement.

Operational round and demonstration

The model operates on daily UTC rounds. Market tabs do not create separate staking pools.

Administration and purpose

Today, BETTEX combines DeFi and AI, with founders initially handling administration. The vision is to replace all administration with AI over time and become fully DeFAI. The token is community-based, without a company, foundation, salaries or service fees. Resources serve the collective; wallets remain personal.

Founders initially handle administration. The gradual transition will replace all administration with AI, making BETTEX fully DeFAI, with evidence and limits and no set deadline. This does not imply a transfer of contract ownership.

Community decisions remain undefined, with no DAO structure, token voting, or ownership renunciation.

Founders initiate management. The DeFAI direction envisions trading, governance, risk and treasury subagents toward BETTEX autonomy, with current controls and responsibilities.

Operations focus on transparency and accountability, without guarantees of capital protection or yields.

Token, funding, and burn

1 billion BETTEX cap: 10% public mint, 55% community, 20% founder/team, and 15% investors. The mint funds the project, with price and platform details to be defined.

Public mint on 12/10/2026; System/ALFA and vesting start in March 2027, subject to legal compliance.

Vesting of 900 million BETTEX over 24 months from March 2027: community 550 million, founder/team 200 million, and investors 150 million, in whole groups of 11:4:3. The separate initial cap is 100 million; release does not prove sale or circulation.

100% of community token revenue goes to the treasury, with no service fees. The mint funds the project with accountability; external markets do not replicate the official swap.

Eligible result is split: 50% treasury, 25% staking, 25% buyback. Without eligible weights, reserves, or liquidity, 100% stays in the treasury. An authorized buyback permanently burns BETTEX; the exclusive wallet is not the burn mechanism.

Staking and liquidation

Participants joining during ongoing rounds receive zero profit from that round, only the next. Balances and additions are fixed at the round's opening.

Weight = eligible opening balance x duration. Exits reset the weight and cancel prior unpaid credits; return occurs only in the next round. Additions do not change existing weights. Gross

payment = staking portion x individual weight / sum of eligible weights.

Example: A starts with 1,000 eligible BETTEX; B receives 1,000 at 12:00. With eligible profit of 1,000 USDC and conditions met, the 250 USDC staking portion pays 250 to A and zero to B. In the next round, both eligible from opening and with no exit receive 125 USDC each on new eligible profit of 1,000 USDC. No prior profit is recovered.

Each round pays or does not, without accumulation, reopening or later supplements. Any BETTEX outflow, including partial, resets weight and cancels only still-unpaid rights. Non-executable fractions return to the treasury, without future credit. Received USDC remains personal.

Credit depends on eligibility, authorization, and reconciliation. Round closing does not hold future credits or transfer presumptions.

Only reconciled balances are available. Uncertain transfers do not trigger repeats or recoveries; corrections do not alter personal wallets.

Governance and integrations

Policies evolve via version, with 2-of-3 multisig for custody. Critical changes require 24h notice; routines do not require new signatures; AI does not expand permissions.

Treasury, operating cash, and wallets have clear boundaries. Defensive reserves follow policy without a 50% minimum. Operations require independent risk assessment.

Starknet and Arbitrum One are alternative networks and contract environments. BETTEX is in planning and grant fundraising, with no chosen network or presumed approved grant. Starknet requires Cairo implementation and compatible accounts; Arbitrum uses EVM. Allora is a candidate for inference, not execution. Robinhood Crypto Trading API requires an eligible U.S. account and authorization; it does not prove access to equities. Public Arbitrum/Gamma queries were verified; they do not define the launch network. Other examples without private access are simulations. There have been no real-money operations.

Economic period, settlement and financial closing

The economic period is the UTC interval between 00:00 and 00:00 the next day. The cutoff ends result collection, but payments are linked to the original round regardless of the current period.

Approved policies must set execution windows, deadlines, and sources. Without validated parameters, distribution is not authorized. Closure occurs upon the end of the window or completion of payments.

Weights are calculated post-cutoff on eligible balances. Entries await the next round; exits nullify weights. Post-cutoff exits cancel pending rights without altering results of new rounds.

Settlement decisions fix beneficiaries and weights, considering confirmed exits. Subsequent

exits cancel credits without redistribution or new splits. Historical records and current weights are distinct.

Calculation and execution are part of the current round. Financial closure eliminates unsent rights; ongoing payments remain in reconciliation. There is no reopening or post-closure credit.

Payment plans follow deterministic order and use atomic execution when validated for the network. If there is partial processing, they publish who received, who did not, and the cause; failures may cause definitive loss of unsent portions at closing, and that risk must be disclosed in advance.

BETTEX exit and payment order

Network order prevails over backend messages. BETTEX exits before USDC receipt cancel rights. Equal timestamps or insufficient evidence suspend finalization.

Bank reserves do not prevent external transfers. Eligibility requires on-network validation with sortable events. Isolated off-chain checks do not guarantee automatic payment.

Canceling rights does not reverse transfers or prove USDC recovery. Reconciliations with improper receipt generate treasury losses without charging the participant or restoring credits.

Settlement costs and temporal origin

Costs belong to the period of occurrence, not the payment round. Round and economic period records must be distinct to avoid double counting.

Before authorizing the split, reserve principal and the cost cap for each asset and project liquidity after all disbursements. A cost reserve is not an incurred expense. Identify its source and authorization; do not silently deduct costs from the participant’s right or the exclusive repurchase portion. Reconcile differences between reserved and actual cost; surplus is not new profit. Without sufficient budget and coverage, do not authorize the split.

External costs are not BETTEX service fees. Settlement rules do not allow using the treasury for general expenses or changing the 50%/25%/25% split.

The round profit is not a capital recovery.

There is no loss compensation or historical equity peak requirement; profits can be distributed if liquidity and reserves exist.

Eligibility, exposure and game conditions

Burn Lottery limits one free number per wallet with BETTEX in staking, using a verifiable snapshot and a unique identifier per wallet and draw. Post-cutoff transfers do not generate new numbers. The budget considers multiple wallets per person; this is not protection against

multiple identities.

The Burn Lottery prize and the costs of the draw require an approved source and coverage before accepting entries. The paid BETTEX are burned and do not finance the prize. Payment, burn reference and entry generation must have a single effect and a verifiable recovery mechanism; if this link cannot be guaranteed, do not accept payments. The regulation informs the draw, verifiable randomness, fault handling and the impossibility of undoing a burn by simple adjustment.

Double 2X requires a mandate, maximum bet, aggregate budget, reserve for simultaneous wins, time limit, verifiable randomness, and failure procedure before opening. The treasury reserves the 2x payout considering the received stake and the additional portion, without using staking, buyback, or other committed resources.

The USDC limit is based on confirmed yields, not token identities. Outflows reduce the limit; external deposits and wins do not increase it. Reserves prevent reuse, the limit never exceeds free USDC balance, and insufficient evidence blocks the bet.

The rule of one play every rolling 24 hours applies to the official wallet linked to the account; changing session, device, or recovering access does not reset the period. It is not a person-proven limit: multiple wallets count in the aggregate budget. Register the start once before execution; an uncertain attempt does not allow another play or release the reserve by presumption.

The 100% RTP is theoretical and gross: it does not cover gas or randomness. Games have their own ledger, reconciled with the treasury’s assets; they do not count as strategy profit eligible for the split and do not use the exclusive buyback budget, but they do affect reserves and liquidity.

Authentication and legal eligibility

Wallet authentication does not prove civil identity, residence, or eligibility. KYC and territorial controls remain mandatory when required. The visual demo does not offer financial operations.

Legal investigation defines controls for mint, games, and integrations. External providers do not waive BETTEX obligations. Without validation, operation is restricted; financial access is not promised without documents.
